

# So Far...

- ▶ It's time for
  - Unsupervised learning
    - We are only given inputs
    - Goal: find “interesting patterns”
    - Discovering clusters
      - Clustering
    - Discovering latent factors
      - Dimensionality reduction
      - Topic modeling
      - Matrix factorization

# Topic Modeling

# Text Analysis

[www.betaversion.org/~stefano/linotype/news/26/](http://www.betaversion.org/~stefano/linotype/news/26/)

- ▶ Text data
  - Web page
  - Emails
  - Documents
  - ...

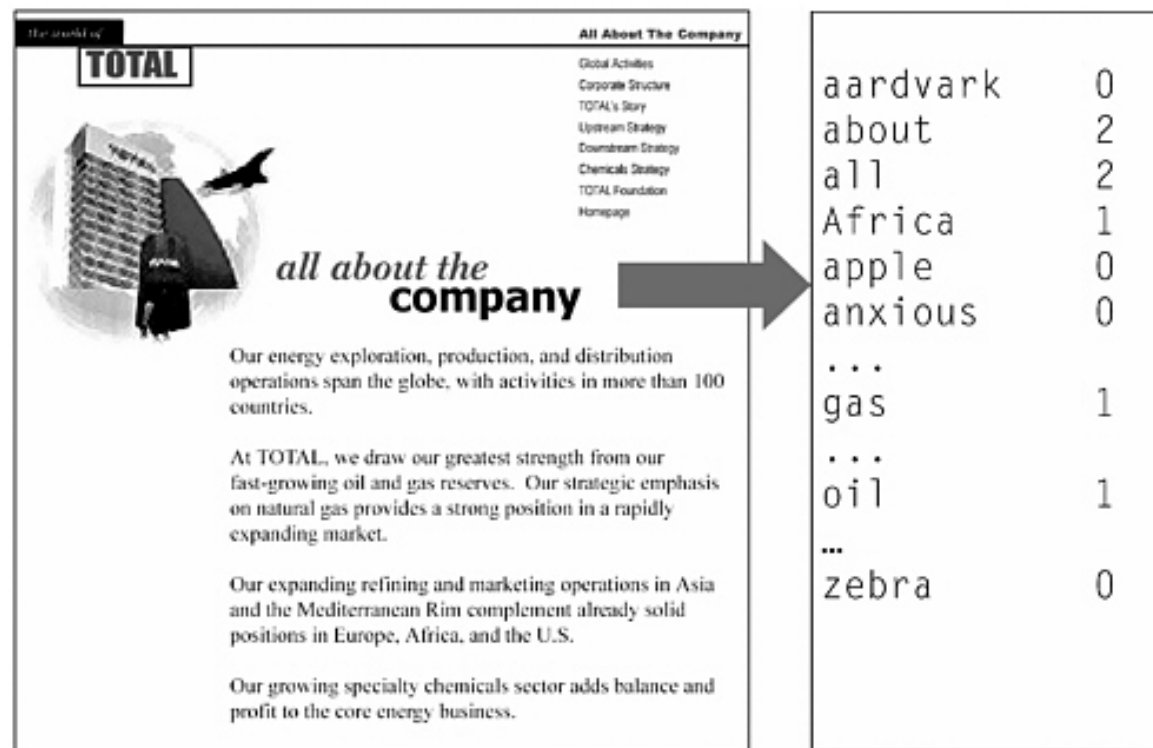

# Bag-of-Words (BOW)

- ▶ Assumes order of words has no significance  
e.g., the term “home made” has the same probability as “made home”
- ▶ It is a simplifying assumption used in natural language processing and information retrieval

# Salton's Vector Space Model (Prior to 1988)

- Represent each document by a high-dimensional vector in the space of words

# Document-Term Matrix

D = Document collection

W = Lexicon/Vocabulary

intelligence

	$d_I$					

# Query

- Compute the similarity between *queries*( $q$ ) and *documents*( $d$ )

$$\cos(\mathbf{q}, \mathbf{d}) = \frac{\mathbf{q}^T \mathbf{d}}{\|\mathbf{q}\| \|\mathbf{d}\|}$$

Simple, intuitive

Fast to compute, because both  
they are sparse

Retrieval Methods

- Rank documents according to similarity with query
- Term weighting schemes, for example, TF-IDF

# A 100 Million<sup>ths</sup> of a Typical Document-Term Matrix

Typical:

- Number of documents  $\approx 1.000.000$
- Vocabulary  $\approx 100.000$
- Sparseness  $< 0.1 \%$
- Fraction depicted  $\approx 1e-8$

**A** =

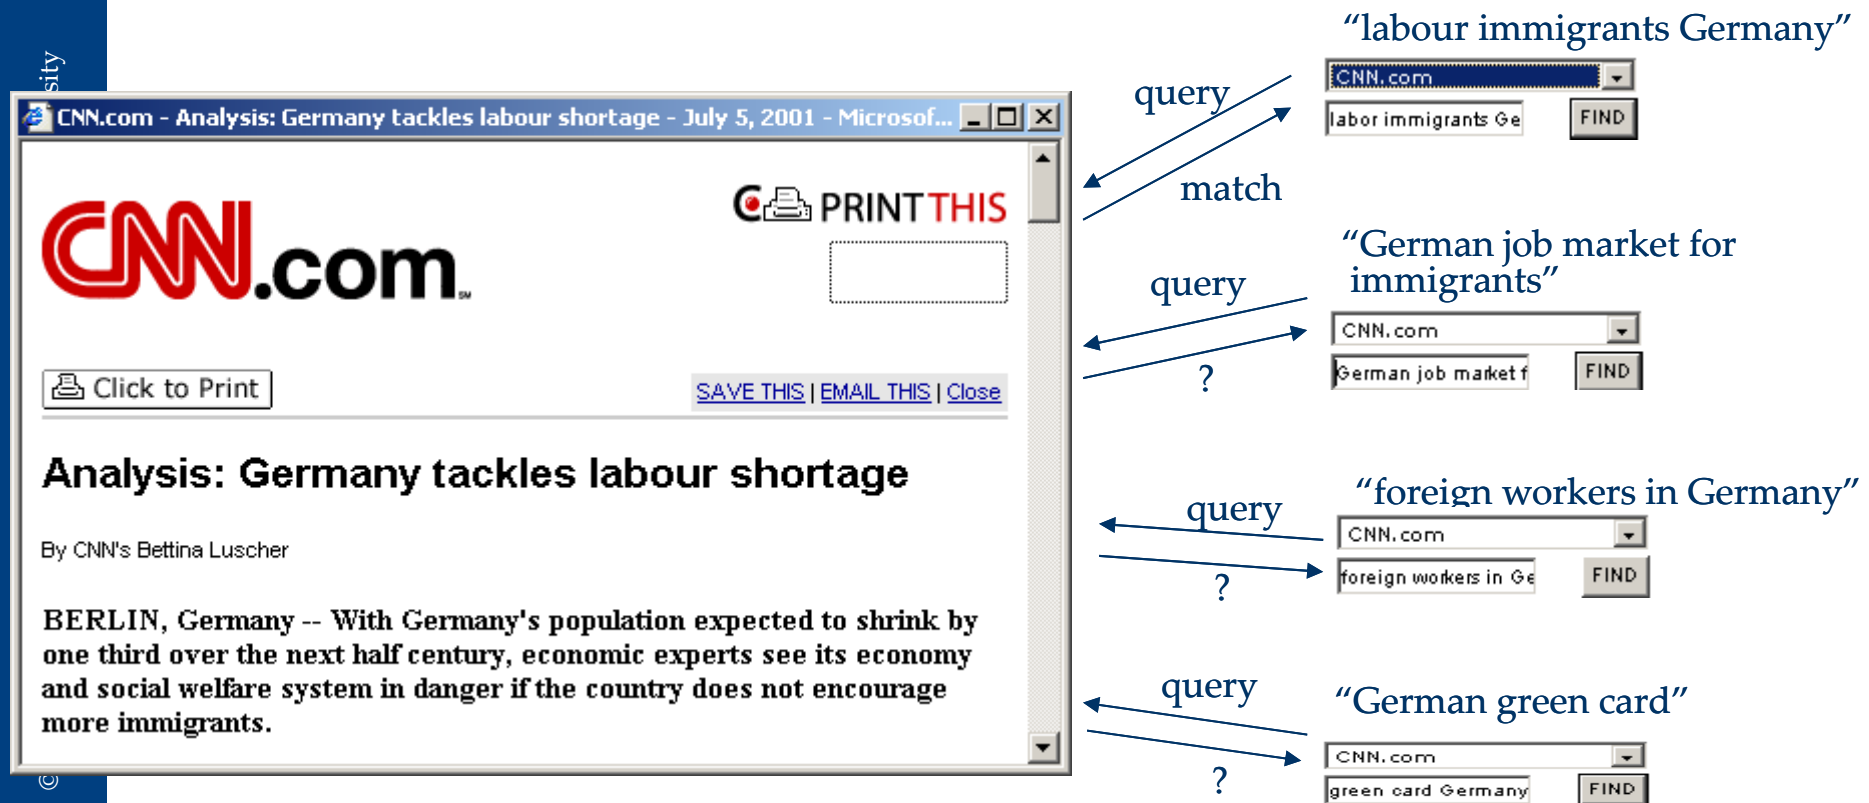

# Robust Information Retrieval — *Beyond Keyword-based Search*

## Vocabulary Mismatch Problem

- ▶ different people using different vocabulary to describe the same concept
- ▶ matching queries and documents based on keywords is insufficient

# The lost meaning of words

- ▶ Polysemy: words with multiple meanings
  - The vector space model is unable to discriminate between different meaning of the same word.

$$\text{sim}(\mathbf{d}, \mathbf{q}) < \cos \left( \angle \left( \vec{\mathbf{d}}, \vec{\mathbf{q}} \right) \right)$$

- ▶ Synonymy: separate words that have the same meaning.
  - No associations between words are made in the vector space representation

$$\text{sim}(\mathbf{d}, \mathbf{q}) > \cos \left( \angle \left( \vec{\mathbf{d}}, \vec{\mathbf{q}} \right) \right)$$

There is a disconnect between topics and words

# Language Model Paradigm in IR

- Probabilistic relevance model

- Random variables

$R_d \in \{0, 1\}$  : relevance of document  $d$

$q \subseteq \Sigma$  : query, set of words

- Bayes' rule

probability of generating a  
query  $q$  to ask for relevant  $d$

prior probability of relevance for  
document  $d$  (e.g. quality, popularity)

$$P(R_d = 1|q) = \frac{P(q|R_d = 1) \cdot P(R_d = 1)}{P(q)}$$

probability that document  $d$   
is relevant for query  $q$

# Language Model Paradigm

$$P(R_d = 1|q) \propto \underbrace{P(q|R_d = 1)}_{(2)} \underbrace{P(R_d = 1)}_{(1)}$$

- ① ▶ First contribution: **prior probability of relevance**
  - simplest case: uniform (drops out for ranking)
  - **popularity**: document usage statistics (e.g. library circulation records, download or access statistics, hyperlink structure)
- ② ▶ Second contribution: **query likelihood**
  - query terms  $q$  are treated as a **sample** drawn from an (unknown) relevant document

# Language Model Paradigm

Query generation model: how might a query look like that would ask for a specific document?

- Maron & Kuhns: Indexer **manually** assigns probabilities for pre-specified set of tags/terms
- Ponte & Croft: **Statistical estimation** problem

Think of a relevant document. Formulate a query by picking some of the keywords as query terms.

environment logging ban

Google Search I'm Feeling Lucky

$$P(q|R_d = 1)$$

Environmentalists are blasting a Bush administration proposal to lift a ban on logging in remote areas of national forests, saying the move ignores popular support for protecting forests.

# Query Likelihood

$$P(q|R_d = 1) \equiv P(q|d)$$

- ▶  $q = (w_1, \dots, w_q)$
- ▶ Independent Assumption

$$P(q|d) = \prod_{w \in q} P(w|d)$$

$$P(w|d)?$$

# Naive Approach

Documents

Terms

Maximum Likelihood Estimation

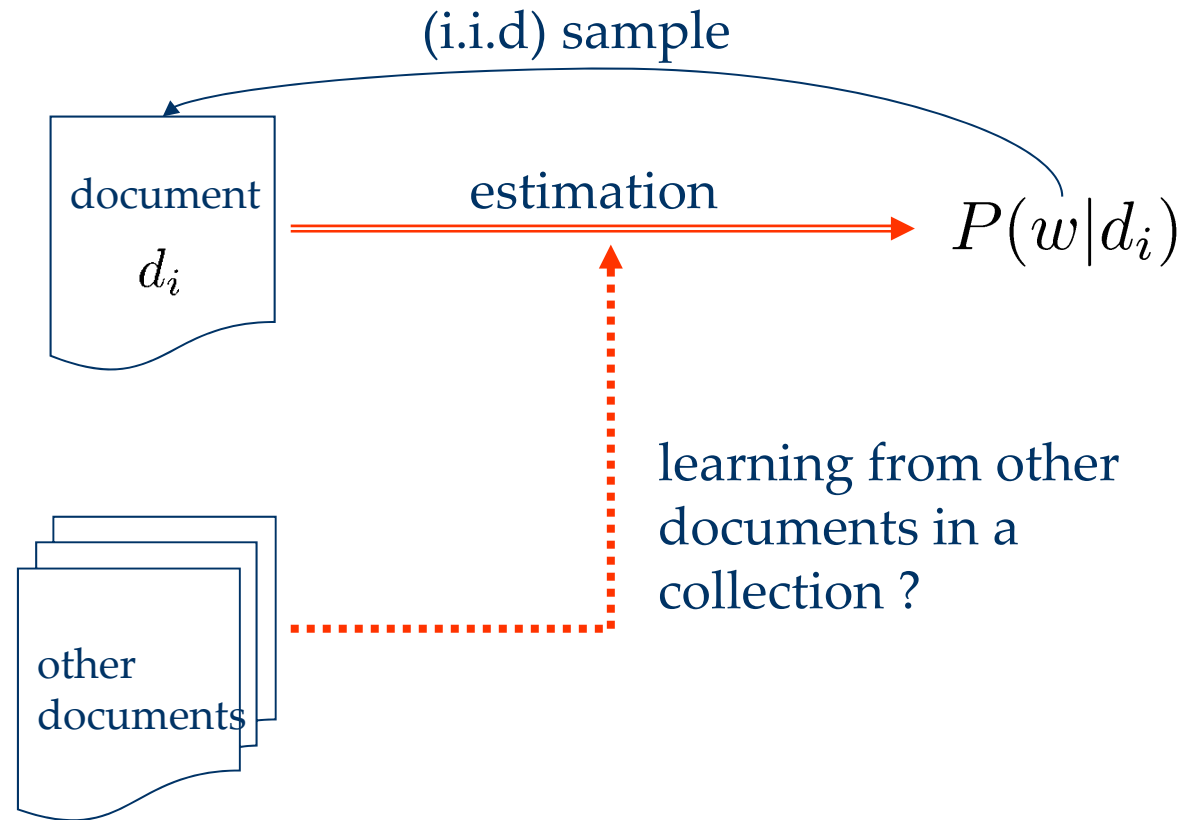

number of occurrences  
of term  $w$  in document  $d$

$$\hat{P}(w|d) = \frac{n(d, w)}{\sum_{w'} n(d, w')}$$

Zero frequency problem: terms  
not occurring in a document get  
**zero** probability

# Estimation Problem

- **Crucial question:** In which way can the document collection be utilized to improve probability estimates?

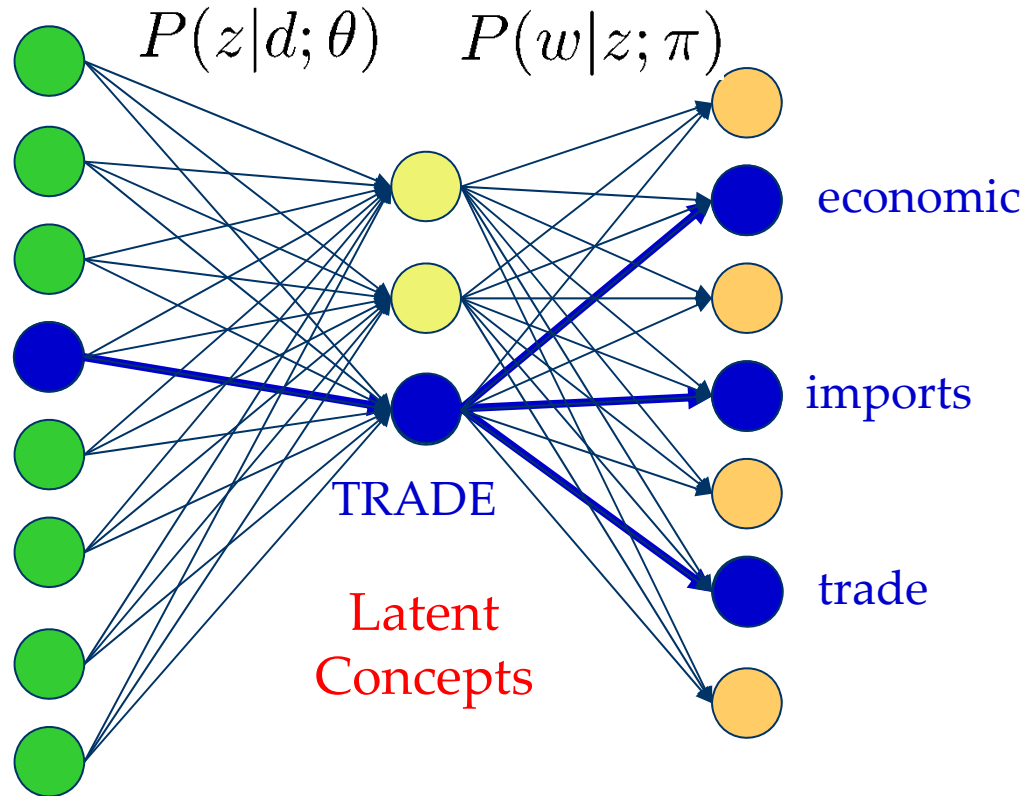

# Probabilistic Latent Semantic Analysis

Documents

Terms

$$\hat{P}(w|d) = \sum_z P(w|z)P(z|d)$$

Concept expression probabilities are estimated based on all documents that are dealing with a concept.

“Unmixing” of superimposed concepts is achieved by statistical learning algorithm.

# Probabilistic Latent Semantic Analysis

- ▶ PLSA evolved from Latent semantic analysis, adding a sounder probabilistic model
- ▶ It was introduced in 1999 by Thomas Hofmann (UAI'99)
- ▶ It is related to non-negative matrix factorization (NMF)

# pLSA – Latent Variable Model

- Structural modeling assumption (**mixture** model)

$$\hat{P}_{\text{LSA}}(w|d) = \sum_z P(w|z; \theta) P(z|d; \pi)$$

Document  
language model

Latent concepts  
or topics

Concept expression  
probabilities

Document-specific  
mixture proportions

Model fitting

# pLSA via Likelihood Maximization

## ► Log-Likelihood

$$l(\theta, \pi; \mathbf{N}) = \sum_{d, w} n(d, w) \log \left( \sum_z P(w|z; \theta) P(z|d; \pi) \right)$$

Diagram illustrating the components of the log-likelihood function:

- $\text{argmax}$  points to the parameters  $(\hat{\theta}, \hat{\pi})$ .
- $\sum_{d, w} n(d, w)$  is labeled "Observed word frequencies".
- $\sum_z P(w|z; \theta) P(z|d; \pi)$  is labeled  $\hat{P}_{\text{LSA}}(w|d)$  and "Predictive probability of pLSA mixture model".

- **Goal:** Find model parameters that maximize the log-likelihood, i.e. maximize the average predictive probability for observed word occurrences (**non-convex optimization problem**)

# EM Algorithm: Derivation

- ▶ Q-parameterized lower bound on log-likelihood

$$l(\theta, \pi; Q) = \sum_{\langle d, w, r \rangle} \sum_z Q_r(z) \log \frac{P(w|z; \theta) P(z|d; \pi)}{Q_r(z)}$$

observed pairs with index r

Q distribution

- ▶ Follows from **Jensen's inequality**

$$\begin{aligned} l(\theta, \pi) &= \sum_{\langle d, w, r \rangle} \log \sum_z Q_r(z) \frac{P(w|z; \theta) P(z|d; \pi)}{Q_r(z)} \\ &\geq \sum_{\langle d, w, r \rangle} \sum_z Q_r(z) \log \frac{P(w|z; \theta) P(z|d; \pi)}{Q_r(z)} = l(\theta, \pi; Q) \end{aligned}$$

# Expectation Maximization Algorithm

- **E step**: posterior probability of latent variables (“concepts”)

$$P(z|d, w) = \frac{P(z|d; \pi)P(w|z; \theta)}{\sum_{z'} P(z'|d; \pi)P(w|z'; \theta)}$$

Probability that the occurrence of term  $w$  in document  $d$  can be “explained” by concept  $z$

- **M step**: parameter estimation based on “completed” statistics

$$P(w|z; \theta) \propto \sum_d n(d, w) P(z|d, w),$$

how often is term  $w$   
associated with concept  $z$  ?

$$P(z|d; \pi) \propto \sum_w n(d, w) P(z|d, w)$$

how often is document  $d$   
associated with concept  $z$  ?

The William Randolph Hearst Foundation will give \$1.25 million to Lincoln Center, Metropolitan Opera Co., New York Philharmonic and Juilliard School. “Our board felt that we had a real opportunity to make a mark on the future of the performing arts with these grants an act every bit as important as our traditional areas of support in health, medical research, education and the social services,” Hearst Foundation President Randolph A. Hearst said Monday in announcing the grants. Lincoln Center’s share will be \$200,000 for its new building, which will house young artists and provide new public facilities. The Metropolitan Opera Co. and New York Philharmonic will receive \$400,000 each. The Juilliard School, where music and the performing arts are taught, will get \$250,000. The Hearst Foundation, a leading supporter of the Lincoln Center Consolidated Corporate Fund, will make its usual annual \$100,000 donation, too.

$P(w|z)$  Matrix

# Variations of pLSA

- ▶ Hierarchical extensions:
  - Asymmetric: MASHA ("Multinomial Asymmetric Hierarchical Analysis")
  - Symmetric: HPLSA ("Hierarchical Probabilistic Latent Semantic Analysis")
- ▶ Manifold regularizer:
  - Probabilistic Dyadic Data Analysis with Local and Global Consistency
- ▶ Generative models:
  - **Latent Dirichlet allocation** - adds a Dirichlet prior on the per-document topic distribution, trying to address an often-criticized shortcoming of PLSA, namely that it is not a proper generative model for new documents and at the same time avoid the overfitting problem.
